Optimized DenseNet Architecture for Efficient Classification of Encrypted Internet Traffic

Abstract

The increasing reliance on Internet-based services has rendered secure and efficient network traffic classification critical.Conventional methods for categorising traffic, such as port and payload methods, often struggle with the challenges posed by encrypted traffic.Deep learning techniques have emerged as a predominant method for traffic classification given their success in domains such as image recognition, document analysis, and genomics. This research proposes an enhanced DenseNet architecture that leverages deep learning to accurately classify encrypted Internet traffic categories.This approach introduces a compression layer into the DenseNet architecture to address the co-adaptation problem as a result of the information flow and optimise the accuracy of the CNN.An Intrusion detection dataset from the Canadian Institute of Cybersecurity was used to evaluate the architecture.The optimised DenseNet architecture was evaluated using metrics such as precision, recall, accuracy, F1-Score, False Positive Rate and Area under the ROC Curve. experimental results show that the approach can distinguish various encrypted Internet traffic categories

Keywords: Convolutional neural network, Internet, Traffic, Classification, DenseNet

INTRODUCTION

Internet traffic classification is a vital aspect of network management and security.As the volume and complexity of Internet traffic continue to expand, efficient and accurate classification methods are essential for distinguishing various applications that utilise the Internet, which is useful for operations such as network optimisation, security monitoring, and quality of service management [1].Conventional approaches to traffic classification, such as port-based and payload-based methods, have become less effective because of the widespread use of encryption and dynamic port allocation [2].

Consequently, machine learning techniques, particularly deep learning models, have gained prominence in recent years owing to their capacity to analyse complex patterns in network traffic data [3].These advanced methods can extract salient features from raw packet data or flow statistics, enabling a more precise classification of Internet traffic even in the presence of encryption [4].The development of sophisticated classification algorithms continues to be an active area of research, with ongoing

efforts to enhance the accuracy, scalability, and adaptability to evolving network protocols and applications.

Deep learning approaches for encrypted traffic classification have demonstrated the most promising results for Internet traffic classification.Owing to successes recorded in tasks such as image classification, voice recognition, and video classification, convolutional neural networks (CNN) have been utilised for Internet traffic classification.One of the most prominent variants of CNN is the DenseNet architecture [5], which enables information propagation through all the layers of the network; however, a significant drawback of the architecture is that as information is passed from the input to the output layer of the network, it can result in the detection of the same features by neurones, thereby resulting in reduced network capacity utilisation [6][7].This study addressed this drawback by introducing a compression layer into the DenseNet architecture to prune redundant neurones in the fully connected layer of the architecture.

The contributions of this study are as follows.

- An enhanced DenseNet architecture with a neuron pruning layer for efficient encrypted internet traffic classification
- A classifier that can accurately distinguish between encrypted Internet traffic categories
- Performance comparison of the proposed architecture with the conventional DenseNet architecture.

The paper is organised as follows. A review of the literature, methodology, results, and discussions are presented.

2. Literature review

The DenseNet architecture was developed to ensure the maximum information flow between the various layers of the CNN architecture.It uses a feedforward architecture, in which each layer receives input feature maps from the preceding layers and passes its feature maps to all subsequent layers. Features are not combined through summation but through concatenation.Researchers have introduced various strategies to address the limitations of DenseNet architecture.Approaches involving supervised and semi-supervised learning have been used [8], while parameter-efficient fine-tuning methods aim to decrease computational resource usage [9].Efforts are also

being made to improve the interpretability of deep-learning models for encrypted traffic classification [10].

[11] stacked convolution layers to enhance feature extraction in the DenseNet architecture and mitigate redundancies.Squeeze excitation modules were employed to represent the interdependencies of salient feature maps. [12] incorporated PSA modules into the DenseNet architecture to improve computational efficiency by dividing the convolution kernels in the Dense PSA block into asymmetric convolutions. [13] utilised a squeeze and excitation module to model the interdependencies between the features of different convolutional layers. [14] introduced a variant of DenseNet inspired by ResNet that substitutes concatenation operations within dense blocks to reduce the model complexity and number of parameters. [15] employed dense blocks to modify the convolution layers in MobileNet, resulting in a higher recognition accuracy. [16] combined DenseNet and LSTM for multivariate tasks. However, this approach has the limitation of high computational time. [17] enhanced the DenseNet architecture using sliding dense blocks to reduce redundancies in the network.

Several researchers have applied the DenseNet architecture to Internet Traffic Classification tasks. [18] utilised a rap-DenseNet framework for network traffic classification.A limitation of this approach is its high computational intensity. [19] incorporated a normalisation layer into the DenseNet architecture for data stabilisation and enhanced the convergence speed. [20] employed a convolutional neural to classify Internet Applications.The technique achieved high accuracy; however, it has the limitation of misclassifying encrypted internet traffic. [21] utilised a fully connected neural network and a 1-dimensional convolutional neural network for classifying the Internet traffic payload.This approach achieved an accuracy of 96%.However, this method is also computationally intensive. [22] employed an ensemble of CNNs to classify network traffic in the Cambridge dataset.An accuracy of 98% is achieved.However, this approach was susceptible to overfitting. [23] proposed a deep learning-based framework for encrypted network traffic that utilises stacked autoencoders, multiperceptrons, and convolutional neural networks.This method achieved low accuracy.

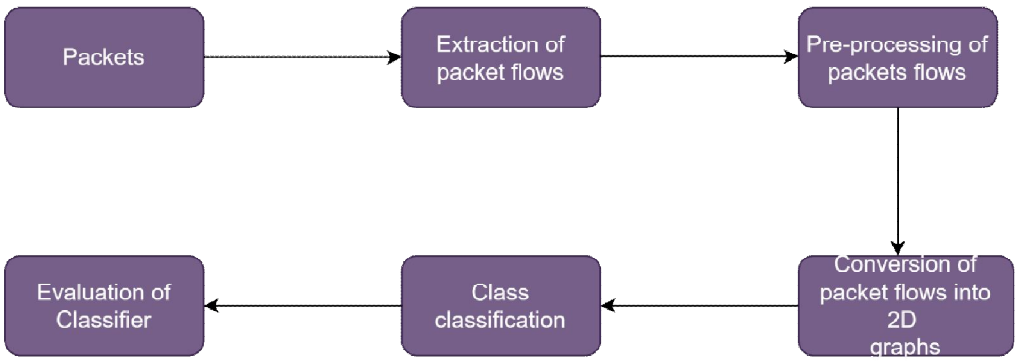
The reviewed studies presented various techniques that have used DenseNet and other CNN variants for classification; however, a common limitation is the susceptibility to overfitting and the high computational overhead involved in training

and deploying the DenseNet model.This study seeks to address this issue by integrating a compression layer that reduces the number of neurons by using neuron pruning.

3. Methodology

The methodology of this study focuses on the development of an enhanced DenseNet architecture for classifying encrypted Internet traffic. This technique addresses the challenges posed by traditional traffic classification techniques when dealing with encrypted data streams. The DenseNet architecture is enhanced by adding a compression layer for neuron pruning.The pruning of neurons is modelled as a tradeoff problem in which neurons are pruned withoutsacrificing the classification performance.The approach proposed in this study incorporates key improvements, such as the removal of redundant neurons in the neural network using the Upper Confidence Bound Multi-Armed Bandits algorithm to boost the classification performance of the neural network.The following subsections describe the dataset preparation, network architecture, training, and evaluation metrics used in this study.Figure 1 illustrates the key stages involved in the implementation of the optimised DenseNet architecture.

Figure 1: Process flow of Internet traffic classification



Dataset

The Intrusion Detection dataset (ISCX) 2016 from the Canadian Institute of Cybersecurity was used to assess the deep-learning-based classification method.The

ISCX-VPN dataset comprises Internet traffic transmitted through an encrypted Internet connection.Within the ISCX VPN category, six traffic categories are captured: VoIP, Streaming, Email, Chat, Peer-to-peer (P2P) traffic, and File Transfer. The categories of the ISCX dataset are shown in the Table 3.1 below

Table 1: Internet traffic categories and applications

Traffic Category	VPN
Voice over IP (VoIP)	Google Hangouts, VoipBuster and Skype
Streaming	Netflix, YouTube and Vimeo
Email	Thunderbolt, SMTP, POP3 and Gmail
Chat	Facebook, Google Hangouts, Skype, IAM and ICQ
Peer to Peer (P2P)	Bittorrent and uTorrent

The dataset comprises packet capture files corresponding to specific application categories

Pre-processing and Graph Construction

The ISCX Packets with similar 5-tuple attributes {source IP, source port, destination IP. Destination port protocol}.The image construction approach used in [24] was adopted in this study, and packets from the ISCX dataset were converted to packet flows with a size of 100 bytes.These packets were then converted into flow-based two-dimensional histograms.The histograms were constructed by plotting the packet-arrival time on the X-axis and the packet size for packets in a packet flow on the Y-axis.Figure 2 illustrates the histograms for various categories captured from the ISCX dataset.

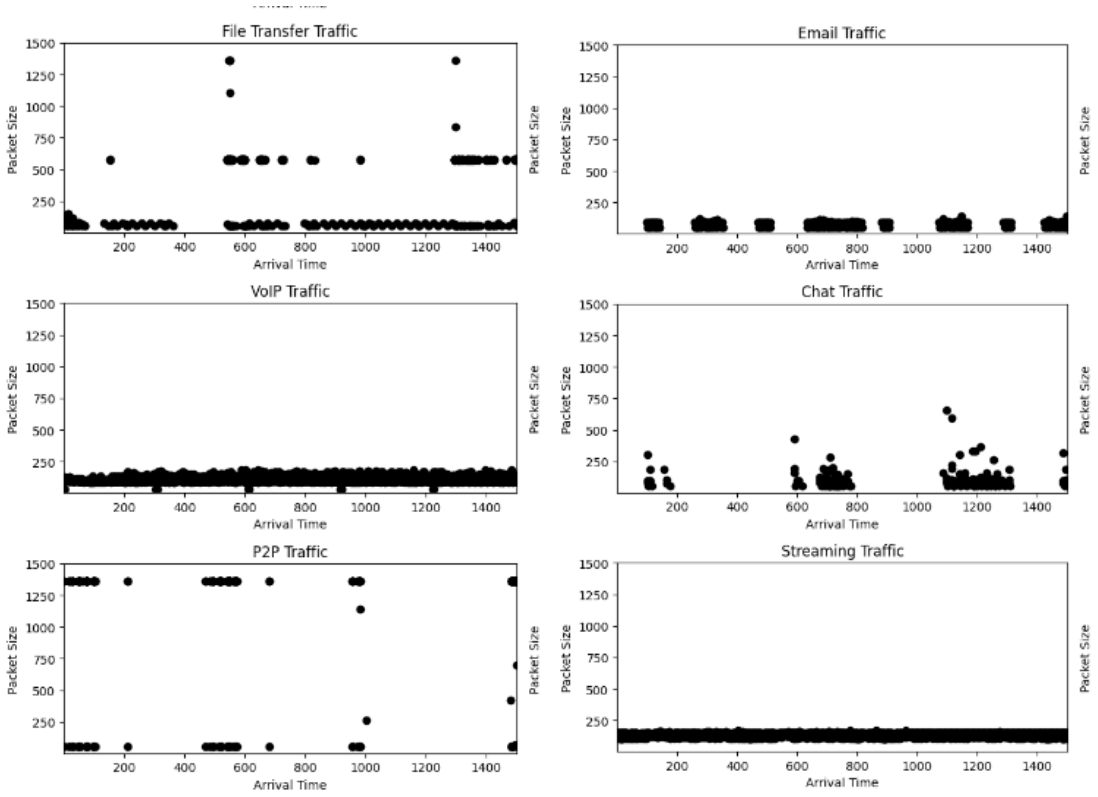


Figure 2: Two-dimensional histograms constructed for Chat, Email, File Transfer, VoIP, P2P and Streaming categories

Network Architecture

The DenseNet architecture comprises convolution, pooling, and fully connected layers with each utilising a non-linear transformation whereH_l = indexes the layer H_l. Transformation operations such as convolution, pooling, batch normalization, andrectified linear units are performed at each respective layer. The pooling layers in the architecture are divided into multiple dense blocks.These operations are condensed into multiple densely connected *blocks*.Figure 3 illustrates the DenseNet architecture with three dense blocks.

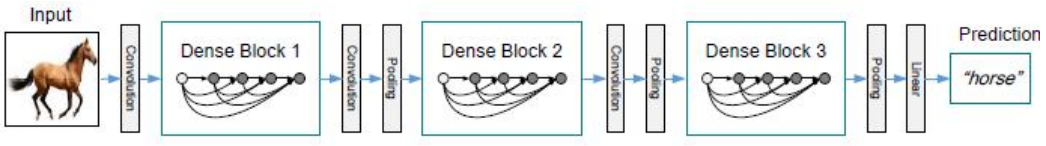

Figure 3: DenseNet Architecture (Huang et al. (2016))

Figure 4 depicts the compression layer added to the DenseNet architecture in the optimisedDenseNet architecture.

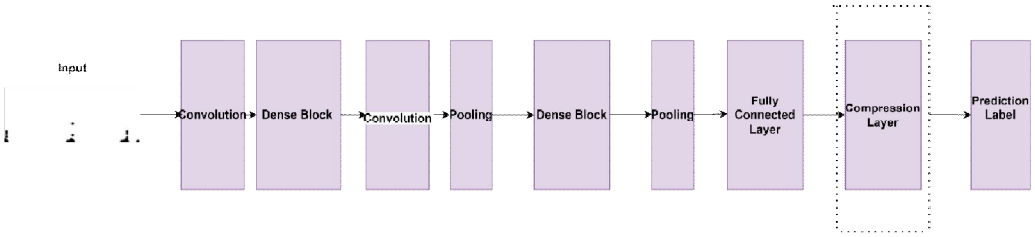

Figure 4: Enhanced DenseNet Architecture with Compression Layer

The three major components of the proposed architecture are discussed below:

Convolutional Layer: The convolutional layer is a fundamental part of the CNN.An input tensor is transformed into an output tensor by convolving the input with the filters. It is performed for input images with a size $W_1 \times H_1 \times C_1$ and accepts four hyper-parameters namely: the number of filters, their spatial extent, the zero padding between the borders of the input and a stride with which filters are applied to each image.

Pooling Layer: The pooling layers reduce the size of the representations with a fixed downsampling transformation.Each channel in the input is independent of the others and spatially downsampled.

Compression Layer: The DenseNet architecture consists of a compression layer that is used to reduce the number of feature maps. However, this approach relies on an arbitrary setting of the compression factor.In this study, the neurons in the fully connected layers were pruned using the Upper Confidence Multi-Armed Bandits Algorithm which was integrated into the enhanced DenseNet.This approach provides a more efficient means of reducing the number of feature maps, thereby compressing DenseNet without degrading classification performance.

Experimental Setup

The dataset used in this study was stored in Google Drive.A Google Colaboratory environment was used to train and evaluate the architecture to enable the use of its free GPU resources.Empirical tests were conducted to compare enhanced and conventional DenseNet architectures.The DenseNet classifier was trained using stochastic gradient descent with an initial learning rate set to 0.1, and The RelU activation function and cross-entropy loss function were used to minimise loss.The dataset was divided into 80% for training and 20% for testing.

Results and Discussion

Conventional and enhanced DenseNet architectures were evaluated. The two architectures were evaluated using performance metrics such as precision, recall, F1 Score, Area under the ROC Curve, and False Positive Rate. Table 2 shows the performance of the Conventional DenseNet architecture in the evaluation metrics. The Peer-to-peer Category recorded near-perfect results for all the metrics.Overall, the classifier provided a balance between precision and recall and effectively controlled the false positive rates.The Chat category displayed the lowest classification performance, a phenomenon that can be explained by the heterogeneous nature of Chat traffic.

Table 2: Performance of Conventional DenseNet Classifier

	Precision	Recall	F1-Score	FPR	TP	TN	FN	FP
Chat	83	89	86	1.91	170	1781	22	34
Email	94	88	91	0.21	63	1888	9	4
File Transfer	91	83	87	1.61	276	1675	55	27
Peer to Peer (P2P)	99	98	98	0.40	453	1498	6	8
Streaming	84	96	89	3.09	268	1683	11	52
VoIP	96	94	95	2.36	721	1230	47	29

Figure 5 illustrates the confusion matrix of the conventional CNN classifier which shows that P2P, Streaming and File Transfer achieved the best results. The classifier distinguishes between the various categories.The conventional classifier struggles to distinguish between VoIP and Streaming categories.

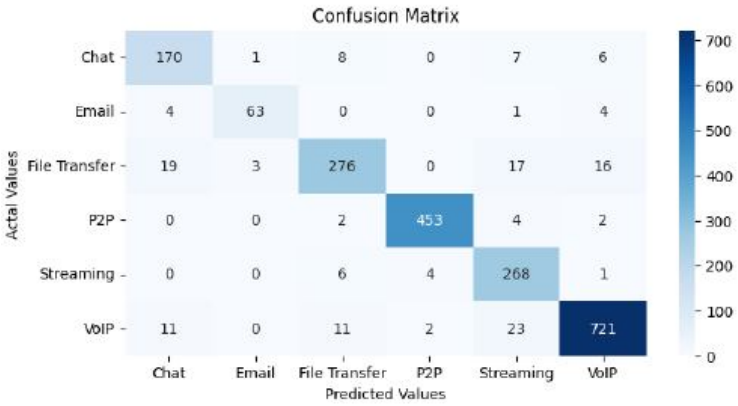

Figure 5: Confusion Matrix for DenseNet Classifier

P2P recorded the highest AUC from the curve in the figure below, closely followed by the Streaming, VoIP, Email and Chat categories.

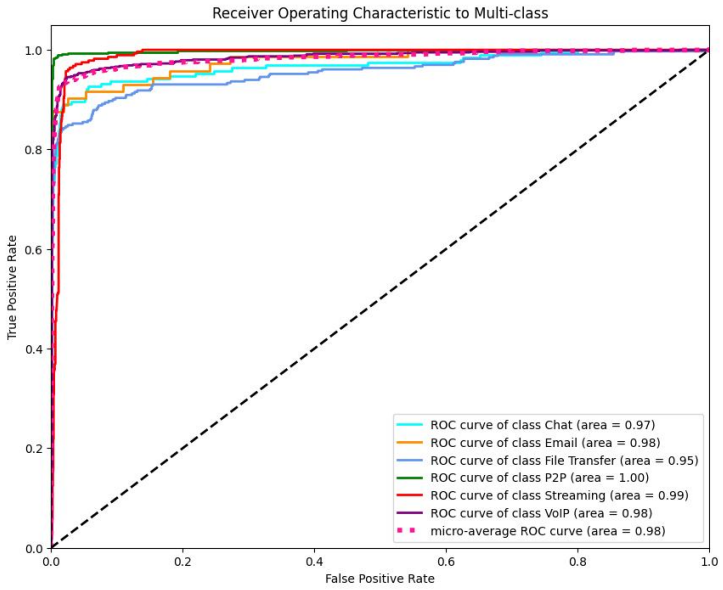

Figure 6: ROC Curve for DenseNet Classifier

The classification performance of the Enhanced DenseNet architecture is also evaluated.Table 3 shows the performance in metrics such as precision, recall, F1 score, area under the ROC curve, and false-positive rate.The enhanced DenseNet architecture outperformed the conventional DenseNet architecture in the file transfer and streaming categories.

Table 3: Performance of Enhanced DenseNet Classifier

	Precision	Recall	F1-Score	FPR	TP	TN	FN	FP
Chat	81	85	83	2.5	213	2472	44	44

Email	90	94	90	0.48	87	2691	8	8
File Transfer	92	85	89	1.83	369	2324	74	74
P2P	99	100	100	0.46	600	2188	15	15
Streaming	83	96	89	1.54	348	2354	24	24
VoIP	99	96	97	0.82	33	1749	66	66

Figure 7 illustrates the confusion matrix, showing that the VOIP category was the most correctly classified category, followed by P2P, File Transfer, Streaming, Chat and Email.Unlike the conventional classifier, the enhanced classifier was able to distinguish between streaming and VoIP categories.

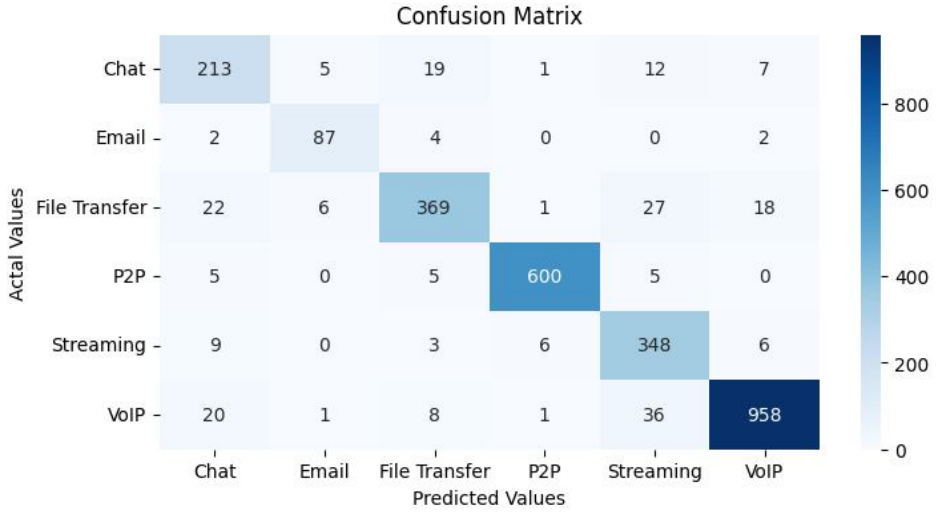

Figure 7: Confusion Matrix for Enhanced DenseNet Classifier

The ROC curves for all categories in Figure 8 showed impressive performances across all traffic categories.P2P had the highest classification, followed by Email, Streaming, Chat and File Transfer.Overall, the classifier maintained high positive rates for all categories while maintaining low false-positive rates.

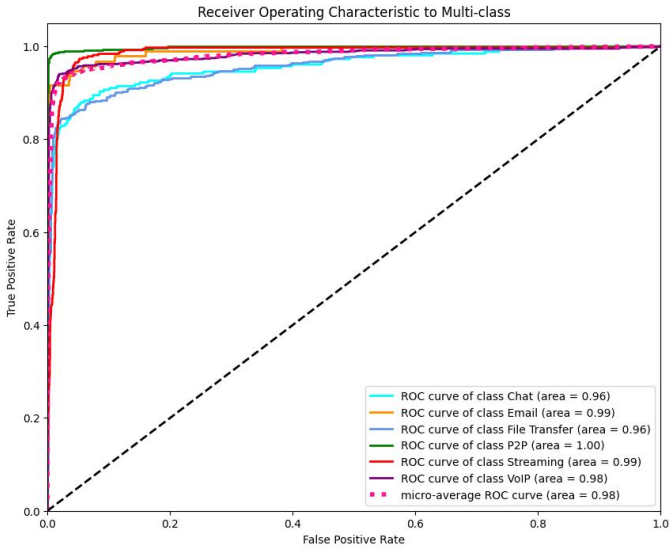

Figure 8: ROC Curve for Enhanced DenseNet Classifier

Conclusion and Future Work

In this study, we introduce a novel DenseNet architecture for identifying Internet traffic application categories.The experimental results demonstrate that the approach used in this study outperforms the conventional DenseNet architecture.The key insight behind the approach utilised is the conversion of traffic flows into two-dimensional graphs.As shown, the optimiseedDenseNet architecture can successfully distinguish encrypted Internet traffic categories.Future studies can further optimise the DenseNet architecture by compressing the input images before they are fed into the classifier.Another approach would be to incorporate modalities, such as payload and temporal features, into the dataset to further improve the classification performance of the classifier.
